What is Form?

- Forms are used to **get input** from the **user** and submit it to the **web server** for **processing**.
- A form is an **HTML tag** that contains graphical user interface **items (elements)** such as **textbox, check boxes, radio buttons** etc.
- The form is defined using the **<form>...</form>** tags and GUI items are defined using **form elements** such as **input**.
- Forms come in handy when developing **flexible and dynamic applications** that accept user input.
- Forms can be used to **edit already existing data** from the database.
- The PHP superglobals **\$_GET** and **\$_POST** are used to collect form-data.
- Both **GET** and **POST** create an array [e.g. array(key1 => value1, key2 => value2, key3 => value3, ...)]. This array holds key/value pairs, where **keys are the names of the form controls** and **values are the input data from the user**.

What is Form?

- The diagram below illustrates the form handling process.

- Both GET and POST are treated as `$_GET` and `$_POST`.

A Sample Form – POST Method

```
<!DOCTYPE HTML>
<html>
<body>
<form action="welcome.php" method="post">
Name: <input type="text" name="name"><br>
E-mail: <input type="text" name="email"><br>
<input type="submit">
</form>
</body>
</html>
```

A screenshot of the HTML form rendered in a web browser. It shows two text input fields. The first field is labeled 'Name:' and contains the text 'Mahesh'. The second field is labeled 'E-mail:' and contains the text 'abcd@andc.du.ac.in'. Below the email field is a grey 'Submit' button.

Name: Mahesh
E-mail: abcd@andc.du.ac.in
Submit

```
<html>
<body>
Welcome <?php echo $_POST["name"]; ?><br>
Your email address is: <?php echo $_POST["email"]; ?>
</body>
</html>
```

A screenshot of the output generated by the PHP script. It displays two lines of text: 'Welcome Mahesh' and 'Your email address is: abcd@andc.du.ac.in'.

Welcome Mahesh
Your email address is: abcd@andc.du.ac.in

GET VS POST Methods

POST

Values not visible in the URL

Has not limitation of the length of the values since they are submitted via the body of HTTP

Has lower performance compared to Php_GET method due to time spent encapsulation the Php_POST values in the HTTP body

Supports many different data types such as string, numeric, binary etc.

Results cannot be book marked

GET

Values visible in the URL

Has limitation on the length of the values usually 255 characters. This is because the values are displayed in the URL. Note the upper limit of the characters is dependent on the browser.

Has high performance compared to POST method dues to the simple nature of appending the values in the URL.

Supports only string data types because the values are displayed in the URL

Results can be book marked due to the visibility of the values in the URL

GET VS POST Methods

FORM SUBMISSION POST METHOD

```
<form action="registration_form.php" method="POST">  
  First name: <input type="text" name="firstname"><br>  
  Last name: <input type="text" name="lastname">  
  <br>  
  <input type="hidden" name="form_submitted" value="1"/>  
  <input type="submit" value="Submit">  
</form>
```

Submission URL does not show form values

localhost/tuttis/registration_form.php ☆

FORM SUBMISSION GET METHOD

```
<form action="registration_form.php" method="GET">  
  First name: <input type="text" name="firstname"><br>  
  Last name: <input type="text" name="lastname">  
  <br>  
  <input type="hidden" name="form_submitted" value="1"/>  
  <input type="submit" value="Submit">  
</form>
```

SUBMISSION URL SHOWS FORM VALUES

localhost/tuttis/registration_form.php?firstname=Smith&lastname=Jones&form_submitted=1 ☆

Lab Exercise No. 1

//Input a String

```
<!Doctype html>
```

```
<head>
```

```
<title>PHP program1 </title>
```

```
</head>
```

```
<body>
```

```
<form method="POST" action="revstr.php">
```

Enter a String:

```
<input type="text" name="str" required>
```

```
<input type="submit" value="SUBMIT">
```

```
</form>
```

```
</body>
```

```
</html>
```

//Reverse of String

```
<?php
```

```
$str1=$_POST['str'];
```

```
echo "Original String = ".$str1."<br/>";
```

```
$rstr1=strrev($str1);
```

```
echo "Reverse String = ".$rstr1."<br/>";
```

```
?>
```

Practice Set No. 16

// PHP code to get the Fibonacci series using recursion

```
<?php
```

```
// Recursive function for fibonacci series.
```

```
function Fibonacci($number) {
```

```
    // if and else if to generate first two numbers
```

```
    if ($number == 0)
```

```
        return 0;
```

```
    else if ($number == 1)
```

```
        return 1;
```

```
    // Recursive Call to get the upcoming numbers
```

```
    else
```

```
        return (Fibonacci($number-1) +
```

```
                Fibonacci($number-2));
```

```
}
```

```
// Driver Code
```

```
$number = 10;
```

```
for ($counter = 0; $counter < $number; $counter++){
```

```
    echo Fibonacci($counter), ' ';
```

```
}
```

```
?>
```
